Type 2405 Pressure Reducing Valve

Self-operated Pressure Regulators · ANSI version

CE

Application

Pressure reducing valve for set points from **0.075 to 150 psi** · Nominal size **NPS ½ to 2** [1] · Pressure rating **Class 125 to 300** · Suitable for gases at temperatures from **–5 to +140 °F** · **32 to +300 °F** [2]

This regulator is used to control the pressure of flammable gases used as a source of energy, e.g. in boilers, driers, vaporizers, heat exchangers or industrial ovens. Alternatively, it can control the compressed air supply in process engineering applications.

An additional application of the regulator is the pressure control of inert gas used for inerting or blanketing reaction or storage tanks to protect the product in the tank from oxidation, explosion or escaping. To achieve an economical consumption of the inert gas, its pressure must be controlled to always remain slightly higher than atmospheric pressure while the tank is being filled or emptied.

Special features

- Low-maintenance regulators functioning as proportional or two-step controllers
- Compact regulator design providing excellent control accuracy
- Internal set point springs with set point adjustment using a nut on the actuator
- Spring-loaded, single-seated valve balanced by a balancing diaphragm
- External connection of a control line
- Meets strict fugitive emission requirements
- Minimum leakage class IV

Version

Pressure reducing valve with proportional control action

Valves in NPS ½ to 2 · Flanged connections · Soft-seated plug · Body made of cast iron, cast steel or cast stainless steel

Pressure reducing valve with two-step control mode

Valves in NPS 1½ and 2 · Flanged connections · Soft-seated plug · Body made of cast iron, cast steel or cast stainless steel

Fig. 1: *Type 2405 Pressure Reducing Valve*

Special versions

- FDA version [3]
- NACE version for sour gas applications
- Version with force limiter (for higher pressures across the operating diaphragm)
- Actuator with seal and leakage line connection
- Version with connected control line. Pressure tapped directly at the valve body; optionally also with pressure gauge

1) NPS ½ and ¾ not in Class 125
2) For unbalanced versions with FKM diaphragm and FKM soft seal
3) This version is not suitable for direct contact with products manufactured in the food and pharmaceutical industries. It can only be used close to the product.

Edition February 2025

Principle of operation

The medium flows through the regulator in the direction indicated by the arrow. The position of the plug (3) determines the cross-sectional area of flow between the plug and the seat (2).

– **Pressure reducing valve with proportional control action (see Fig. 3)**

In the pressureless state (control line not connected and no pressure applied) the valve is opened by the force of the set point springs (27). The spring force is adjustable at the set point adjuster (30).

The downstream pressure p_2 to be controlled is tapped downstream of the regulator and transmitted over an external control line to the control line connection (9) on the actuator housing (20) where it is converted into a positioning force by the diaphragm plate (18) with operating diaphragm (21). The diaphragm moves the plug over the plug stem (4) depending on the force of the set point springs.

When the force resulting from the downstream pressure p_2 rises above the spring force adjusted at the set point springs, the valve closes proportionally to the change in pressure.

In the version with pressure balancing, the forces produced by the upstream and downstream pressures acting on the plug are eliminated by the balancing diaphragm (8). The plug is fully balanced.

– **Pressure reducing valve with two-step control mode (see Fig. 2)**

The regulator (nominal sizes NPS 1½ and 2, C_V 20 and 37 with set point ranges from 0.075 to 0.87 psi) operates as a two-step controller.

A differential pressure of at least 23.5 psi is required for troublefree operation.

In the idle state, the valve is closed when the pressure in the bottom actuator chamber is equal or higher than the set point. The set point is adjusted by tensioning the set point spring (27) at the set point adjuster (30).

The upstream pressure p_1 is routed through a hole in the plug stem to the chamber of the plug balancing unit above the balancing diaphragm (8).

The valve is pressure-balanced in this way.

The required closing force of the plug is generated by the compression spring (542) in the chamber.

If the downstream pressure p_2 being controlled drops below the lower switching point of the adjusted set point, the force created by the diaphragm (21) is lower than the force of the set point spring (27). This causes the diaphragm plate (18), which is fastened to the actuator stem (540), to be pushed down moving towards the plug. This results in a force being exerted on the tappet, which is part of the assembly (535) of the internal bypass valve.

The pressure in the balancing chamber is relieved to the downstream side.

The balancing pressure drops until it reaches the level of the downstream pressure p_2. As a result, the upstream pressure exerted on the plug is able to fully open the valve opposing the force of the compression spring (542).

If the downstream pressure p_2 starts to rise again and reaches the upper switching point of the adjusted set point, the diaphragm plate (18) and actuator stem (540) with it are lifted. The internal bypass valve closes and the upstream pressure p_1 starts to build up again in the chamber of the plug balancing unit above the balancing diaphragm (8). The pressure-balanced state of the valve is restored and the compression spring (542) causes the plug to close.

The two-step control mode is determined by a switching accuracy of ≤0.022 psi between the upper and lower switching point.

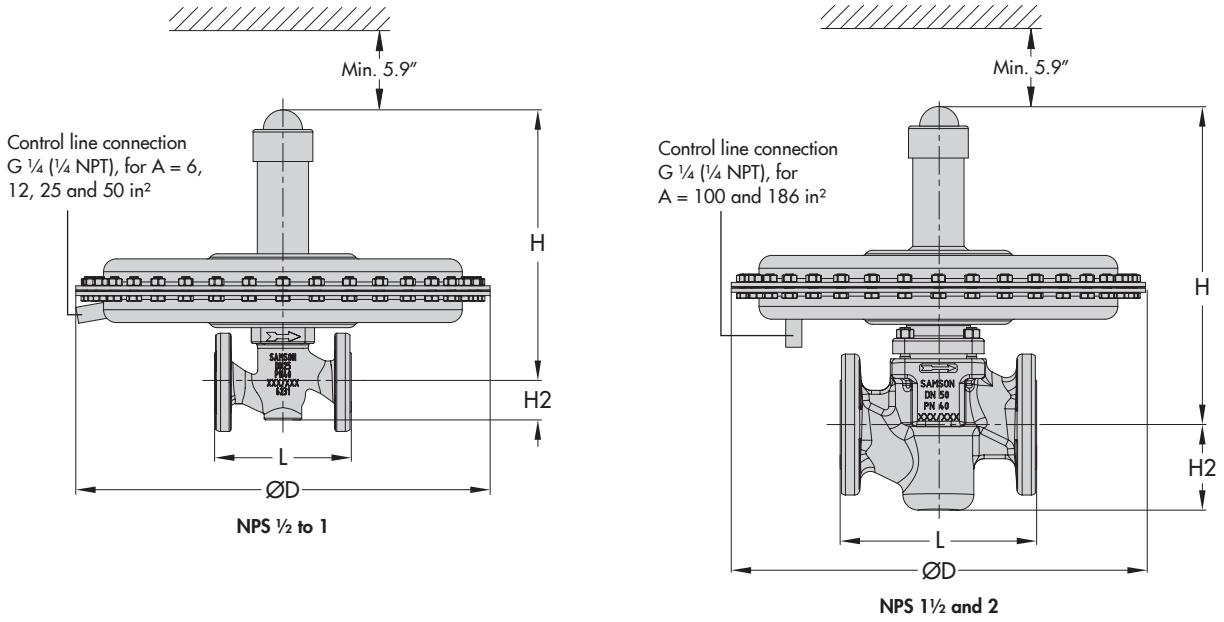
Dimensions



The control line connection is turned by 90° in the drawing.
The connection is normally located opposite the side with the arrow indicating the direction of flow.
An adapter G ¼ to ¼-18 NPT (order no. 0230-3417) must be ordered separately.

Weight [1] in lb (approx.)								

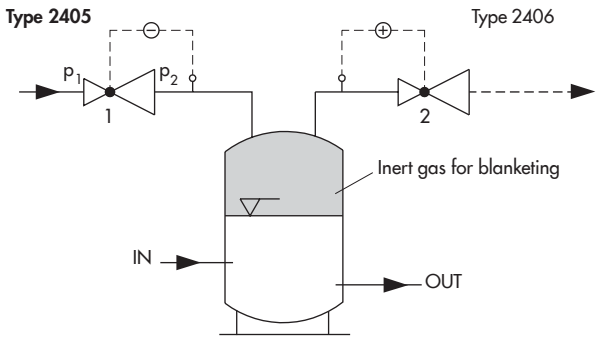
[1] Body made of A216 WCC and A351 CF8M: +10 %

Installation

The regulator is preferably to be installed in horizontal pipelines:

- Actuator housing on top, actuator facing upwards
- The direction of flow must match the direction indicated by the arrow on the body.
- In applications in which the blanketing gas can liquefy, condensate may form in the control line, causing damage to the regulator. To allow condensate to run back into the tank, install the control line with an approximate 10 % slope to the pressure tapping point at the tank.
- Distance between the pressure tapping point and regulator min. 6x NPS

In exceptional cases, the regulator can also be installed in vertical pipelines with the direction of flow from the top (see ▶ EB 2520 for more details).



If the pressure p of the inert gas in the tank falls below the set point p_2 adjusted at the **Type 2405** Pressure Reducing Valve (1), it opens to allow more gas to enter the tank. The valve (1) closes again when the pressure p of the blanketing gas rises to the adjusted set point p2.
If the pressure is too high, the inert gas is vented off over the Type 2406 Excess Pressure Valve (2).

Fig. 7: *Sample application, Type 2405 used for tank blanketing*
